

Half the burden reduction arrives within roughly a decade in every stratum

Across the twenty strata the halfway point falls between 2.5 and 11.5 years (panel C, shaded band = first decade). Whether herds go on to reach freedom of infection depends on herd size and within-herd transmission.

Panels A and B: one line per herd size, labelled at $R_0 = 2$ where the strata separate. Panel C: segments run from the year half the burden reduction is achieved to the year half of herds are free of infection; a concentric marker means both fell in the same year, and a segment ending flat at 50 years did not reach that second milestone within the simulated horizon.
